ON THE MULTIPLICATIVE PARTITION FUNCTION

By

Ryuji KANEIWA

1. Introduction.

Let n be a positive integer. A *multiplicative partition* of the number n is a representation of n as the product of any number of integers that are greater than 1. Thus

$$24 = 2 \cdot 12 = 3 \cdot 8 = 4 \cdot 6 = 2 \cdot 2 \cdot 6 = 2 \cdot 3 \cdot 4 = 2 \cdot 2 \cdot 2 \cdot 3$$

has 7 multiplicative partitions (cf. the table annexed at the end of this paper). Let us denote the number of multiplicative partitions of n by X(n), namely

$$X(n) = \sum_{n=2^{l_{2_3}l_{3_4}l_{4\dots,l_2}, l_3, l_4,\dots\geq 0} 1 \qquad (n > 1);$$

X(1) is defined to be 1. This arithmetical function, we call it the multiplication partition function, was introduced by MacMahon [6] who noted that the function X(n) has a generating function

(1)
$$G(s) \stackrel{\text{def}}{=} \sum_{n=1}^{\infty} X(n) n^{-s} = \prod_{m=2}^{\infty} (1 - m^{-s})^{-1}, \quad \text{Re } s > 1.$$

Making use of this relation, Oppenheim [7], [8] found an asymptotic formula

$$\sum_{n \leq x} X(n) = \frac{x e^{2\sqrt{\log x}}}{2\sqrt{\pi}(\log x)^{3/4}} \left\{ 1 + \sum_{k=1}^{N-1} \frac{\varepsilon_k}{(\log x)^{k/2}} + O_N\left(\frac{1}{(\log x)^{N/2}}\right) \right\},$$

where the ε_k are certain constants, for each N and all large x. He also obtained a better approximation

(2)
$$\sum_{n \leq x} X(n) = x \sum_{k=0}^{\infty} d_k \frac{I_{k+1}(2\sqrt{\log x})}{\sqrt{\log x^{k+1}}} + O\left(x \frac{e^{\sqrt{\log x}}}{(\log x)^{3/8}}\right)$$

to the sum $\sum_{n \leq x} X(n)$, where the $I_k(x)$ are modified Bessel functions, and the numbers d_k are the coefficients in the Taylor expansion

(3)
$$\frac{G(s)}{s} e^{-1/(s-1)} = \sum_{k=0}^{\infty} d_k (s-1)^k, \quad |s-1| < \frac{1}{2}.$$

Received June 20, 1983.

In this note, we shall prove (2) with sharper error term. This is the following

THEOREM. We have

(4)
$$\sum_{n \leq x} X(n) = x \sum_{k=0}^{\infty} d_k \frac{I_{k+1}(2\sqrt{\log x})}{\sqrt{\log x}^{k+1}} + O(x e^{-A\sqrt{\log x}}),$$

for any positive A, and sufficiently large $x \ge x_0(A)$.

Concerning the function G(s), we have immediately

(5)
$$\log G(s) = \sum_{m=2}^{\infty} \sum_{k=1}^{\infty} \frac{1}{k} m^{-ks} = \sum_{k=1}^{\infty} \frac{1}{k} \{\zeta(ks) - 1\}, \quad \text{Re } s > 1,$$

where $\zeta(s)$ is the Riemann zeta-function. This last series converges uniformly in any compact subset of the set $\{s; \text{Re } s > 0\} - \{1, 1/2, 1/3, \cdots\}$. The following lemma is due to Oppenheim [8].

LEMMA 1. The function $\log G(s)$ is regular for s > 0 except s=1/n (n=1, 2, ...), where there are simple poles of the function with respective residues $1/n^2$ (n=1, 2, ...). In particular, near the point s=1, we have

(6)
$$\log G(s) = \frac{1}{s-1} + O(s-1).$$

By this lemma, we get the Taylor expansion (3) with

(7)
$$d_0 = 1$$

Moreover Estermann [3] showed that the function G(s) is singular at every point of the imaginary axis.

In order to prove our theorem, in the next section we shall estimate the function

(8)
$$\xi_1(x) = \sum_{n \le x} X(n)(x-n) = \int_1^x \xi_0(u) du$$
, where $\xi_0(x) = \sum_{n \le x} X(n)$,

using the theorem of Hardy and Littlewood (see Chandrasekharan [2]) that

(9)
$$\zeta(s) = O\left(t^{4(1-\sigma)/\log(1/(1-\sigma))} \frac{\log t}{\log \log t}\right),$$

for $t \ge 3$, uniformly for $63/64 \le \sigma < 1$, where $\sigma = \text{Re } s$ and t = Im s. This argument will lead us our estimate (4) of $\xi_0(x)$ in §3. Finally in §4, we shall give the numbers d_k in the Taylor expansion (3) an effective form.

2. Estimation of $\xi_1(x)$.

By Perron's formula, we have

(10)
$$\xi_1(x) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{G(s)x^{s+1}}{s(s+1)} ds \qquad (c>1) \ .$$

It is plain that

$$\sum_{k=2}^{\infty} \frac{1}{k} \{ \zeta(ks) - 1 \} = O(1)$$

for $\sigma = \text{Re } s \ge 2/3$ and all t = Im s. By (5) we have

(11)
$$\log G(s) = \zeta(s) + O(1) \qquad (\sigma \ge 2/3)$$

Let A_1 be any fixed positive number. From (9) we get that for $t \ge 3$,

$$\zeta(s) = O_{A_1}\left(\frac{\log t}{\log \log t}\right)$$

uniformly for $1 - \frac{A_1}{\log t} \le \sigma \le 1$. Thus in the region $t \ge 3$, $1 - \frac{A_1}{\log t} \le \sigma \le 1$, $2/3 \le \sigma$ we have

(12)
$$\log G(s) = O_{A_1}\left(\frac{\log t}{\log \log t}\right).$$

On the other hand for $\sigma \geq 1$, $t \geq 1$, we have

$$(13) \qquad |\log G(s)| \leq |\zeta(s)| + O(1)$$

$$\leq \log t + O(1)$$
 (see [2] p. 34).

We now choose, for given x>1, the curve $\mathcal{C}=\mathcal{C}_1\cup\mathcal{C}_2\cup\mathcal{C}_3$ such that

$$\begin{cases} C_{1} = \left\{ s ; \sigma = 1 - \frac{A_{1}}{\log |t|}, -\infty < t \leq t_{0} \right\}, \\ C_{2} = \left\{ s ; \sigma = \sigma_{0}, |t| \leq t_{0} \right\}, \\ C_{3} = \left\{ s ; \sigma = 1 - \frac{A_{1}}{\log t}, t_{0} \leq t < \infty \right\}, \end{cases}$$

where

$$t_0 = t_0(x) = e^{\sqrt{A_1 \log x}}, \quad \sigma_0 = 1 - \frac{A_1}{\log t_0}.$$

The curve C is oriented by the parameter t. By (10), (12) and (13), we obtain

(14)
$$\xi_1(x) = \operatorname{Res}_{s=1} \frac{G(s)x^{s+1}}{s(s+1)} + \frac{1}{2\pi i} \int_c \frac{G(s)x^{s+1}}{s(s+1)} ds .$$

We divide the integral on the right-hand side into several parts. Let

Ryuji KANEIWA

(15)
$$\frac{1}{2\pi i} \int_{c} \frac{G(s)x^{s+1}}{s(s+1)} ds = E_{1} + E_{2} + \bar{E}_{2} + E_{3} + \bar{E}_{3},$$

where

$$E_{1} = \frac{1}{2\pi} \int_{-3}^{3} \frac{G(s)x^{s+1}}{s(s+1)} dt \qquad (s = \sigma_{0} + ti),$$

$$E_{2} = \frac{1}{2\pi} \int_{3}^{t_{0}} \frac{G(s)x^{s+1}}{s(s+1)} dt \qquad (s = \sigma_{0} + it),$$

$$E_{3} = \frac{1}{2\pi i} \int_{C_{3}} \frac{G(s)x^{s+1}}{s(s+1)} ds,$$

and \overline{E}_j (j=2, 3) are complex conjugates of E_j .

(i) Estimation of E_1 . Let $s = \sigma_0 + it$ ($|t| \leq 3$). By lemma 1 we have

$$\log G(s) = \frac{1}{s-1} + O(1)$$
,

Re log
$$G(s) = \frac{\sigma_0 - 1}{(\sigma_0 - 1)^2 + t^2} + O(1)$$
.

Since $\sigma_0 - 1 < 0$, G(s) = O(1). Thus we have for x > 1,

(16)
$$E_1 = O(x^{\sigma_0 + 1}) = O(x^2 e^{-\sqrt{A_1 \log x}})$$

(ii) Estimation of E_2 . Let $s = \sigma_0 + it$ ($3 \le t \le t_0$). From (9), for sufficiently large $x \ge x_1(A_1)$ we have

$$\begin{aligned} \zeta(s) &= O\left\{ \exp\left(\frac{4A_1}{\log\log t_0 - \log A_1}\right) \frac{\log t}{\log\log t} \right\} \\ &= O\left(\frac{\log t}{\log\log t}\right) = O\left(\frac{\log t_0}{\log\log t_0}\right) \\ &= O\left(\frac{\sqrt{A_1}}{\log A_1} \sqrt{\log x}\right) \end{aligned}$$

By (11), we get

$$E_2 = O\left(x^2 \exp\left\{-\left(1 + O\left(\frac{1}{\log A_1}\right)\right)\sqrt{A_1 \log x}\right\}\right)$$

Thus we have for sufficiently large A_1 and $x \ge x_1(A_1)$,

(17)
$$E_2 = O\left(x^2 e^{-\frac{1}{2}\sqrt{A_1 \log x}}\right).$$

(iii) Estimation of $E_{\rm S}.$ Let $\sigma\!=\!1\!-\!\frac{A_{\rm 1}}{\log t}$ $(t\!\geq\!t_{\rm 0}).$ The estimate (12) leads us to

(18)
$$E_{3} = O\left(x^{2} \int_{t_{0}}^{\infty} t^{-3/2} dt\right)$$
$$= O\left(x^{2} e^{-\frac{1}{2}\sqrt{A_{1} \log x}}\right)$$

for sufficiently large $x \ge x_2(A_1)$. By (14)-(18), we obtain the following

Lemma 2.

(19)
$$\hat{\xi}_1(x) = \operatorname{Res}_{s=1} \frac{G(s) x^{s+1}}{s(s+1)} + O(x^2 e^{-A_2 \sqrt{\log x}}),$$

for any positive A_2 and sufficiently large $x \ge x_3(A_2)$.

3. Proof of the theorem.

Let

(20)
$$U(x) \stackrel{\text{def}}{=} \operatorname{Res}_{s=1} \frac{G(s)x^{s+1}}{s(s+1)} \,.$$

Then we have

(21)
$$U'(x) = \operatorname{Res}_{s=1} \frac{G(s)x^s}{s}, \quad U''(x) = \operatorname{Res}_{s=1} G(s)x^{s-1}.$$

Since $\hat{\xi}_0(x)$ is an increasing function, we have

$$\frac{1}{h} \{ \xi_1(x) - \xi_1(x-h) \} \leq \xi_0(x) \leq \frac{1}{h} \{ \xi_1(x+h) - \xi_1(x) \}, \ h > 0 ,$$

by the definition (8). Suppose that

(22)
$$h = h(x) > 0, \quad h = o(x).$$

Then, by (19) we have

$$\xi_1(x \pm h) = U(x \pm h) + O(x^2 e^{-A_1 \sqrt{\log x}})$$

and

$$U(x \pm h) = U(x) \pm hU'(x) + \frac{h^2}{2}U''(x \pm \theta_{\pm}h), \quad 0 < \theta_{+}, \ \theta_{-} < 1.$$

Since

$$\pm \frac{1}{h} \left\{ \xi_1(x \pm h) - \xi_1(x) \right\} = U'(x) \pm \frac{h}{2} U''(x \pm \theta_{\pm} h) + O\left(\frac{x^2}{h} e^{-A_2 \sqrt{\log x}}\right),$$

we have

(23)
$$\xi_0(x) = U'(x) + O\{hU''(x \pm \theta_{\pm}h)\} + O\left(\frac{x^2}{h}e^{-A_2\sqrt{\log x}}\right).$$

In connection with functions U'(x), U''(x), we can show

Lemma 3.

(24)
$$U'(x) = x \sum_{k=0}^{\infty} d_k \frac{I_{k+1}(2\sqrt{\log x})}{(\log x)^{(k+1)/2}},$$

(25)
$$U''(x) \sim \frac{1}{2\sqrt{\pi}} \cdot \frac{e^{2\sqrt{\log x}}}{(\log x)^{3/4}}.$$

PROOF. By the definition of modified Bessel functions $I_n(x)$, we have

$$e^{\frac{1}{s-1}x^{s-1}} = \exp\left\{\sqrt{\log x} \left(\frac{1}{(s-1)\sqrt{\log x}} + (s-1)\sqrt{\log x}\right)\right\}$$
$$= \sum_{n=-\infty}^{\infty} I_n(2\sqrt{\log x}) \{(s-1)\sqrt{\log x}\}^n$$

and

(26) Res
$$e^{1/(s-1)} x^{s-1} (s-1)^k = I_{-k-1} (2\sqrt{\log x}) \sqrt{\log x}^{-k-1}$$
$$= \frac{I_{k+1} (2\sqrt{\log x})}{(\log x)^{(k+1)/2}}.$$

By (3) and (21), we get (24). Next we shall show (25). Let c_k be the constants such that

$$G(s)e^{-1/(s-1)} = \sum_{k=0}^{\infty} c_k (s-1)^k, \qquad |s-1| < 1/2$$

(cf. Lemma 1). Then for some positive constant M,

$$|c_{k}| \leq M^{k}$$
 (k=0, 1, 2, ...)

and we have

$$c_0 = 1$$
.

By (21) and (26), we have

$$U''(x) = \frac{I_1(2\sqrt{\log x})}{\sqrt{\log x}} + E,$$

where

$$E = \frac{1}{2\pi i} \int_{|s|=\rho} e^{1/s} x^s \sum_{k=1}^{\infty} c_k s^k ds \qquad (0 < \rho < 1/2).$$

If $M\rho\!<\!$ 1, we have

$$|E| \leq \frac{M\rho^2}{1 - M\rho} e^{1/\rho} x^{\rho}.$$

By taking $\rho = 1/\sqrt{\log x}$, we obtain

$$U''(x) = \frac{I_1(2\sqrt{\log x})}{\sqrt{\log x}} + O\left(\frac{e^{2\sqrt{\log x}}}{\log x}\right).$$

Since we have, as is well known,

$$I_k(x) \sim \frac{e^x}{\sqrt{2\pi x}}$$

we get (25). This completes the proof.

By using this lemma with

$$h = x e^{-((A_2/2)+1)\sqrt{\log x}}$$
 (see (22))

(23) leads us to

$$\xi_0(x) = x \sum_{k=0}^{\infty} d_k \frac{I_{k+1}(2\sqrt{\log x})}{(\log x)^{(k+1)/2}} + O(xe^{-((A_2/2)-1)\sqrt{\log x}}).$$

Thus our theorem is proved.

REMARK. In our approximation (4), we may conjecture that the best order of the error term would be

$$O\left(\sqrt{x} \ \frac{e^{\sqrt{\log x}}}{(\log x)^{3/4}}\right),$$

for the reason that

$$\operatorname{Res}_{s=1/2} \frac{G(s)x^{s}}{s} = \sqrt{x} \sum_{k=0}^{\infty} d'_{k} \frac{I_{k+1}(\sqrt{\log x})}{2^{k+1}(\log x)^{(k+1)/2}}$$
$$\sim \frac{d'_{0}}{2\sqrt{2\pi}} \sqrt{x} \frac{e^{\sqrt{\log x}}}{(\log x)^{3/4}},$$

where d'_k are defined by

$$\frac{G(s)}{s} e^{-\frac{1}{4(s-(1/2))}} = \sum_{k=0}^{\infty} d'_k \left(s - \frac{1}{2}\right)^k \qquad \left(\left|s - \frac{1}{2}\right| < \frac{1}{6} \right).$$

However, it seems very difficult to prove this.

4. The numbers d_k .

Let γ_n and α_n respectively denote the constants defined by

(27)
$$\gamma_n = \lim_{N \to \infty} \left(\sum_{\nu=1}^N \frac{\log^n \nu}{\nu} - \frac{\log^{n+1} N}{n+1} \right) \qquad (n \ge 0)$$

and

(28)
$$\alpha_n = \sum_{m=1}^n (m-1)! S(n, m) \alpha_n^{(m)} \qquad (n > 0),$$

where

$$\alpha_n^{(m)} = \begin{cases} \sum_{\nu=1}^{\infty} \frac{\log^n(\nu+1)}{\nu(\nu+1)}, & \text{if } m=1, \\ \sum_{\nu=1}^{\infty} \frac{\log^n(\nu+1)}{\nu^m}, & \text{if } m>1, \end{cases}$$

and integers S(n, m) are Stirling numbers of the second kind, that is, defined by the identity

(29)
$$x^{n} = \sum_{m=0}^{n} S(n, m) x(x-1) \cdots (x-m+1) .$$

Then we have the following

PROPOSITION. The numbers d_n can be represented in the form

(30)
$$d_{n} = (-1)^{n} \sum_{m=0}^{n} \sum_{\substack{m=1 \cdots m_{1}+2 \cdots m_{2}+\cdots \\ m_{1}, m_{2}, \cdots \geq 0}} \frac{\beta_{1}^{m_{1}} \beta_{2}^{m_{2}} \cdots}{(1 !)^{m_{1}} m_{1} ! (2 !)^{m_{2}} m_{3} ! \cdots},$$

where $\beta_n = \gamma_n + \alpha_n \quad (n > 0).$

Thus we have

$$d_{0}=1,$$

$$d_{1}=-1-\beta_{1}=-2.18493\cdots,$$

$$d_{2}=1+\beta_{1}+\frac{1}{2}(\beta_{2}+\beta_{1}^{2})=5.48422\cdots,$$

$$d_{3}=-1-\beta_{1}-\frac{1}{2}(\beta_{2}+\beta_{1}^{2})-\frac{1}{6}(\beta_{3}+3\beta_{2}\beta_{1}+\beta_{1}^{3})=-13.80378\cdots,$$
.....

PROOF OF PROPOSITION. It is not difficult to see that β_n and γ_n can be defined alternatively by

(31)
$$\log G(s) = \frac{1}{s-1} + \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} \beta_n (s-1)^n$$

and

(32)
$$\zeta(s) = \frac{1}{s-1} + \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \gamma_n (s-1)^n$$

respectively. We obviously get (30) from (31). And also we have (27) from (32). The latter was found by Stieltjes, Jensen [5], and Briggs-Chowla [1]. Values $(-1)^n \gamma_n/n!$ have been calculated by Gram [4] with 16 decimals. We now have

$$\beta_n = \gamma_n + \alpha_n \qquad (n > 0)$$
,

where

(33)
$$\alpha_n = (-1)^n \sum_{k=2}^{\infty} k^{n-1} \zeta^{(n)}(k) = \sum_{\nu=1}^{\infty} \log^n \nu \sum_{k=2}^{\infty} k^{n-1} \nu^{-k} ,$$

by (5), (31) and (32). It is enough to show (28) from the definition (33) of α_n . We have

$$\sum_{m=1}^{n} (m-1)! S(n, m) \alpha_n^{(m)} = \sum_{\nu=1}^{\infty} \log^n(\nu+1) \left\{ \frac{1}{\nu(\nu+1)} + \sum_{m=2}^{n} (m-1)! S(n, m) \nu^{-m} \right\}$$

We may show, for all positive integers ν ,

(34)
$$\sum_{k=2}^{\infty} k^{n-1} (\nu+1)^{-k} = \frac{1}{\nu(\nu+1)} + \sum_{m=2}^{n} (m-1)! S(n, m) \nu^{-m}.$$

This leads us to (28). Let $f_n(w)$ $(n=1, 2, \dots)$ denote rational functions

$$\frac{w^2}{1+w} + \sum_{m=1}^{n} (m-1) \, ! S(n, m) w^m \, ,$$

and suppose S(n, m)=0 for integers m outside $0 \le m \le n$. If w=z/(1-z) then we have

$$f_{n}(w) = \frac{z^{2}}{1-z} + \sum_{m=2}^{n} (m-1) ! S(n, m)(z+z^{2}+\cdots)^{m}$$

$$= \sum_{k=2}^{\infty} z^{k} \sum_{m=1}^{k} (m-1) ! S(n, m) \frac{m(m+1)\cdots(k-1)}{(k-m)!}$$

$$= \sum_{k=2}^{\infty} z^{k} \frac{1}{k} \sum_{m=1}^{n} S(n, m)k(k-1)\cdots(k-m+1)$$

$$= \sum_{k=2}^{\infty} k z^{n-1} z^{k} \qquad (|z| < 1),$$

by (29). Thus we have (34), on putting $w=1/\nu$. This completes the proof.

REMARK. The author could not find Stieltjes's paper for γ_n , whereas Gram [4] referred to it.

ACKNOWLEDGEMENT. The author wishes to thank Prof. S. Uchiyama, Prof. T. Tatuzawa and Mr. S. Egami for valuable advice.
